Abstract
Three types of suspension of a semi-infinite Bernoulli-Euler beam and a fluid-conveying pipe are considered. It is shown that the environment (i.e. the semi-infinite Bernoulli-Euler beam or the fluid-conveying pipe) adds a fractional derivative into the suspension equation. The eigenvector expansion method based upon transformation of the derived equation into a set of four semidifferential equations is utilised for solving the equations with fractional derivatives.

Key words
fractional derivatives, semi-infinite Bernoulli-Euler beam, fluid-conveying-pipe, half-order differential equation.

1 Introduction
The intent of the presentation is to show that the governing equation for simple mechanical systems may contain fractional derivatives. We consider three types of oscillator to which a semi-infinite Bernoulli-Euler beam is attached. It is shown that if the consideration is limited only to the oscillator, then the environment (i.e. the semi-infinite Bernoulli-Euler beam) adds a fractional derivative into the suspension equation. Another system governed by a differential equation with fractional derivative is the suspension of the fluid-conveying-pipe. The eigenvector expansion method based upon transformation of the equation into a set of four semidifferential equations is utilised for solving the obtained differential equation with fractional derivatives.

2 Three mechanical systems
Consider a Single-Degree-Of-Freedom system and a semi-infinite Bernoulli-Euler beam $x>0$, which is attached to mass $m$ at $x=0$, see Fig. 1.
\[ \mathbf{A}_{\infty} = -E_I \frac{d^3 \pi}{dx^3} = -EI \left[ \lambda'_c A_c + \lambda'_b A_b \right] = -4EI \cdot \beta^3 p \sqrt{p A_l} \cdot \]

As follows from eqn (2.6) \( \mathbf{v}(0, p) = \mathbf{v}(p) = 2A_e \), that allows the latter equation to be rewritten in the following form

\[
\mathbf{A}_{\infty, \phi} = -2EI \cdot \beta^3 p \sqrt{p} \mathbf{v}(p) .
\]

Inserting the latter equation into eqn (2.4) yields

\[ mp^2 \mathbf{v}(p) + 2EI \beta^3 p \sqrt{p} \mathbf{v}(p) = \mathbf{f}(p) .\]

Since the trivial initial conditions were assumed, eqn (2.8) corresponds to the following ordinary differential equation for displacement \( y(t) \)

\[ m \frac{d^2 y}{dt^2} + 2EI \beta^3 \frac{d^{3/2} y}{dt^{3/2}} + cy = f(t) .\]

As seen from eqn (2.9), the dynamics of mass \( m \) is governed by a single differential equation with a fractional derivative.

Another mechanical system governed by the differential equation with a fractional derivative is obtained from the above system if the semi-infinite Bernoulli-Euler beam is clamped to a rigid mass \( m \), rather than it is simply supported. In this case the governing equation is as follows (the derivation is omitted as it is fully analogous to the previous one)

\[ m \frac{d^2 y}{dt^2} + 4EI \beta^3 \frac{d^{3/2} y}{dt^{3/2}} + cy = f(t) .\]

The third mechanical system consists of a disk attached to an angular spring and a semi-infinite Bernoulli-Euler beam, Fig. 2. The beam is supposed to be clamped to the disc in such a way that the angle of rotation of the disk and that of the beam at \( x=0 \) coincide. The differential equation of the disk is given as

\[ J \frac{d^2 \phi}{dt^2} + 2EI \beta^3 \frac{d^{3/2} \phi}{dt^{3/2}} + k \phi = m(t) .\]

where \( J \) is the moment of the mass inertia, \( k \) is the angular stiffness of the spring and \( m(t) \) is the external driving moment. Again, a differential equation with a fractional derivative is obtained however, in contrast to eqs. (2.9)-(2.11), now we have the fractional derivative of the order 1/2.

3 Mechanical system with a pipeline conveying fluid

We consider a pipeline conveying a heavy fluid. The suspension is assumed to be modeled by a spring of stiffness \( c \) and a dashpot \( b \). The mass of the suspension is \( m \) and \( v \) denotes the velocity of the fluid, see Fig. 3.

Omitting the derivation of the differential equation for mass \( m \) we demonstrate the final result for the case of massless pipe, heavy fluid and low velocities

\[ m \frac{d^2 y}{dt^2} + 4EI \beta^3 \frac{d^{3/2} y}{dt^{3/2}} + (b - \rho A_v) \frac{dy}{dt} + cy = f(t) .\]

where \( f(t) \) denotes the distributed external force in the transversal direction.

4 An example of solving the derived differential equation with fractional derivative

We take eqn (3.1) in the case \( f(t)=0 \) and solve it by means of the eigenvector expansion method suggested by Suarez and Shokooh for solving differential equation with fractional derivatives. This method is based upon the transformation of the equations of motions into a set of four first-order semidifferential equations. To this end, we introduce non-dimensional time \( \tau = \frac{kt}{\sqrt{c/m}} \) where \( k = \sqrt{c/m} \) denotes the natural frequency of the suspension. After a little algebra we obtain the equation in terms of the non-dimensional variables

\[ D^2 y + 2\delta D^{3/2} y + \varepsilon D y + y = 0, \quad D = \frac{d}{d\tau} .\]

Here two coefficients

\[ \delta = 2\frac{EI \beta^3}{m\sqrt{k}} \quad \text{and} \quad \varepsilon = \left( \frac{\rho A_v - b}{mk} \right) \]

are responsible for stability or instability of the pipe with the fluid. Figure 4 displays the impulse response function for two set of parameters. Both stable and unstable modes are observable.

5 Conclusion

It is shown that some mechanical systems are governed by differential equations with fractional derivatives. The eigenvector expansion method is used for solving the obtained equations with fractional derivatives and deriving closed-form solutions. For example, this closed form solution is appropriate for obtaining simple formula for the critical velocity for systems conveying fluids.
